STACK

Push: adds an element to the top of the stack.

Pop: removes and returns the top element of the stack.

Peek: returns the top element without removing it.

Is_empty: checks if the stack is empty.

Size: returns the number of elements in the stack.

CODE:

#STACK

class Stack:

def __init__(self):

self.items = []

def is_empty(self):

return len(self.items) == 0

def push(self, item):

```
        self.items.append(item)
def pop(self):
    if not self.is_empty():
        return self.items.pop()
    else:
        raise IndexError("pop from an empty stack")
def peek(self):
    if not self.is_empty():
        return self.items[-1]
    else:
        raise IndexError("peek from an empty stack")
def size(self):
    return len(self.items)
```

Example usage

```
stack = Stack()
print("Is the stack empty?", stack.is_empty()) # Output: True
stack.push(1)
stack.push(2)
stack.push(3)
stack.push(4)
stack.push(5)
stack.push(6)
stack.push(7)
stack.push(8)
stack.push(9)
```

```

stack.push(10)

print("Stack:", stack.items) # Output: [1, 2, 3]

print("Top of the stack:", stack.peek()) # Output: 3

print("Pop:", stack.pop()) # Output: 3 (corrected to call the method)

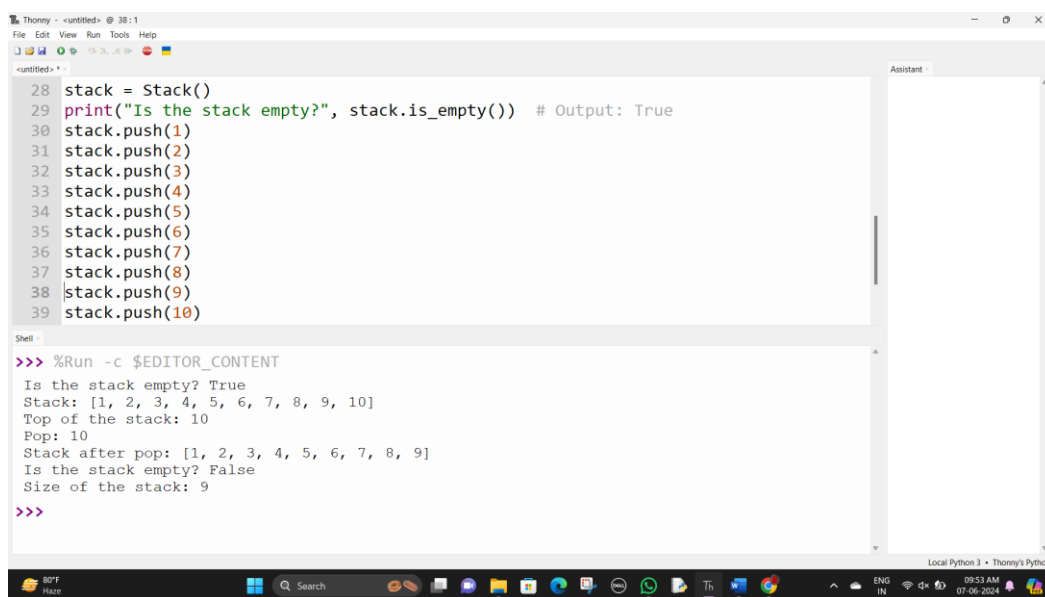

print("Stack after pop:", stack.items) # Output: [1, 2]

print("Is the stack empty?", stack.is_empty()) # Output: False

print("Size of the stack:", stack.size()) # Output: 2

```

OUTPUT:

```

28 stack = Stack()
29 print("Is the stack empty?", stack.is_empty()) # Output: True
30 stack.push(1)
31 stack.push(2)
32 stack.push(3)
33 stack.push(4)
34 stack.push(5)
35 stack.push(6)
36 stack.push(7)
37 stack.push(8)
38 stack.push(9)
39 stack.push(10)

>>> %Run -c $EDITOR_CONTENT
Is the stack empty? True
Stack: [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
Top of the stack: 10
Pop: 10
Stack after pop: [1, 2, 3, 4, 5, 6, 7, 8, 9]
Is the stack empty? False
Size of the stack: 9
>>>

```

STACK USING LINKED-LIST

CODE:

#STACK USING LINKED-LIST

class Node:

```
def __init__(self,data):
```

```
    self.data=data
```

```
    self.next=None
```

class Stack:

```
def __init__(self):
```

```
        self.head=None

def is_empty(self):
    return self.head is None

def push(self,data):
    new_node=Node(data)
    new_node.next=self.head
    self.head=new_node

    while current:
        print(current.data, end=" -> ")
        current=current.next
    print("None")

stack=Stack()
stack.push(1)
stack.push(2)
```

```

stack.push(3)
stack.push(4)
stack.push(5)
stack.push(6)
stack.push(7)
stack.push(8)
stack.push(9)
stack.push(10)
stack.display()

print("Popped:", stack.pop())

print("Peek:", stack.peek())

stack.display()

```

OUTPUT:

The screenshot shows a Python IDE with a code editor and a shell window. The code in the editor implements a stack using a linked list. The shell window shows the output of running the code, which is a linked list of numbers 10 to 1, followed by popping 10, peeking 9, and displaying the final linked list 9 to 1.

```

1 #STACK USING LINKED-LIST
2 class Node:
3     def __init__(self,data):
4         self.data=data
5         self.next=None
6 class Stack:
7     def __init__(self):
8         self.head=None
9     def is_empty(self):
10        return self.head is None
11    def push(self,data):
12        new_node=Node(data)

```

```

>>> %Run -c $EDITOR_CONTENT
10 -> 9 -> 8 -> 7 -> 6 -> 5 -> 4 -> 3 -> 2 -> 1 -> None
Popped: 10
Peek: 9
9 -> 8 -> 7 -> 6 -> 5 -> 4 -> 3 -> 2 -> 1 -> None
>>>

```

QUEUE

CODE:

```
#QUEUE
```

```
class QueueList:
```

```
    def __init__(self):
```

```
        self.items = []
```

```
    def is_empty(self):
```

```
        return len(self.items) == 0
```

```
    def enqueue(self, item):
```

```
        self.items.append(item)
```

```
    def dequeue(self):
```

```
        if not self.is_empty():
```

```
            return self.items.pop(0)
```

```
        else:
```

```
            raise IndexError("dequeue from an empty queue")
```

```
    def peek(self):
```

```
        if not self.is_empty():
```

```
            return self.items[0]
```

```
        else:
```

```
            raise IndexError("peek from an empty queue")
```

```
    def size(self):
```

```
        return len(self.items)
```

```
# Testing the QueueList class
```

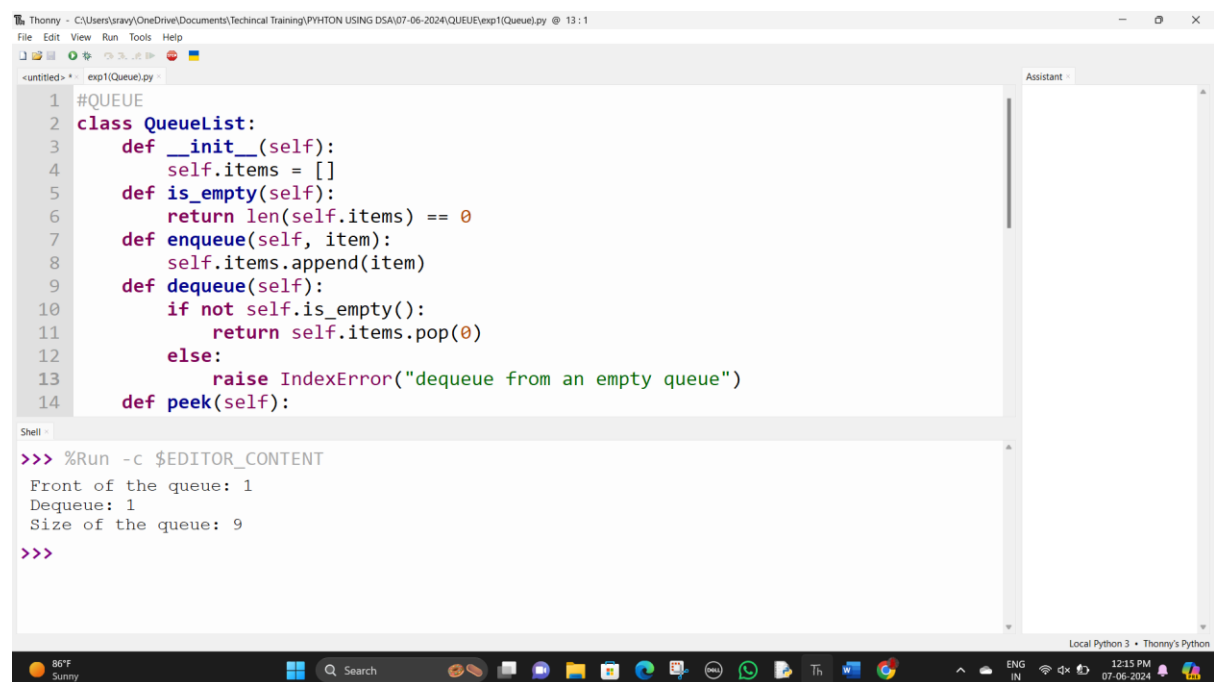

```
queue = QueueList()
```

```
queue.enqueue(1)
```

```
queue.enqueue(2)
```

```
queue.enqueue(3)
queue.enqueue(4)
queue.enqueue(5)
queue.enqueue(6)
queue.enqueue(7)
queue.enqueue(8)
queue.enqueue(9)
queue.enqueue(10)
print("Front of the queue:", queue.peek())
print("Dequeue:", queue.dequeue())
print("Size of the queue:", queue.size())
```

OUTPUT:

The screenshot shows the Thonny Python IDE with a file named 'exp1(Queue).py'. The code defines a 'QueueList' class with methods for enqueue, dequeue, peek, and is_empty. The output in the shell shows the results of running the code: 'Front of the queue: 1', 'Dequeue: 1', and 'Size of the queue: 9'.

```
#QUEUE
class QueueList:
    def __init__(self):
        self.items = []
    def is_empty(self):
        return len(self.items) == 0

TREE

- Tree data structure is a hierarchical structure that is used to represent and organize data in a way that is easy to navigate and search. It is a collection of nodes that are connected by edges and has a hierarchical relationship between the nodes.
- The topmost node of the tree is called the root, and the nodes below it are called the child nodes. Each node can have multiple child nodes, and these child nodes can also have their own child nodes, forming a recursive structure.
- The data in a tree are not stored in a sequential manner i.e., they are not stored linearly. Instead, they are arranged on multiple levels or we can say it is a hierarchical structure. For this reason, the tree is considered to be a **non-linear data structure**.

Representation of Binary Tree

- **Types of Binary Tree:**

- Binary Tree consists of following types **based on the number of children**:
 1. Full Binary Tree
 2. Degenerate Binary Tree
- **On the basis of completion of levels**, the binary tree can be divided into following types:
 1. Complete Binary Tree
 2. Perfect Binary Tree
 3. Balanced Binary Tree

2. Ternary Tree:

→ A Ternary Tree is a tree data structure in which each node has at most three child nodes, usually distinguished as “left”, “mid” and “right”.

3. Generic / N-aryTree:

→ Generic trees are a collection of nodes where each node is a data structure that consists of records and a list of references to its children(duplicate references are not allowed). Unlike the linked list, each node stores the address of multiple nodes.

Special Types of Trees:

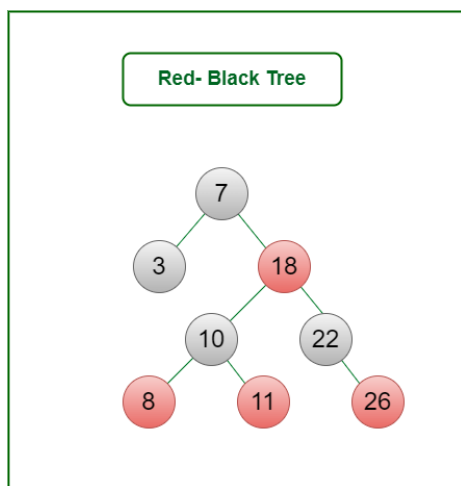

1. Binary Search Tree.

2. AVL-Tree.

3. Red-Black Tree.

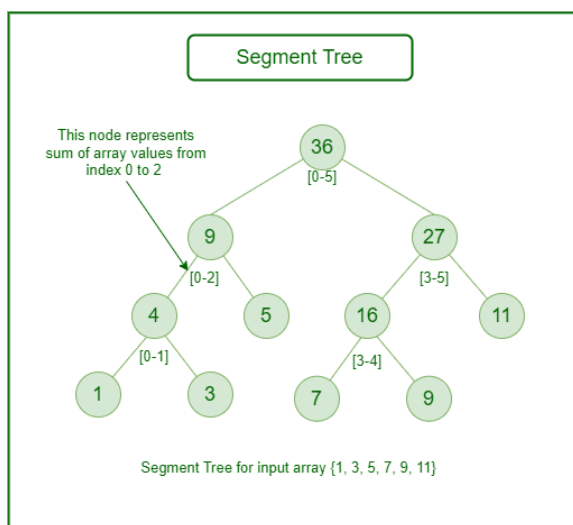

4. B-Tree.

5. B+ Tree.

6. Segment Tree.

In-order Tree Traversal without Recursion: (Left-Root-Right)

OUTPUT= 4->2->5->1->3->6

Step 1:

Leftmost node of the tree is visited

Step 2:

Left subtree of 2 is fully traversed. So 2 is visited next

Step 3:

Right subtree of 2 (i.e., 5) is traversed

Step 4:

Left subtree of 1 is fully traversed. So 1 is visited next

Step 5:

3 has no left subtree, so it is visited

Step 6:

Right Child of 3 is visited

Post-order Traversal of Binary Tree : (Left-Right-Root)

EXAMPLE:

Step 1:

The leftmost leaf node (i.e., 4) is visited first

Step 2:

Left subtree of 2 is traversed. So 5 is visited next

Step 3:

All subtrees of 2 are visited. So 2 is visited next

Step 4:

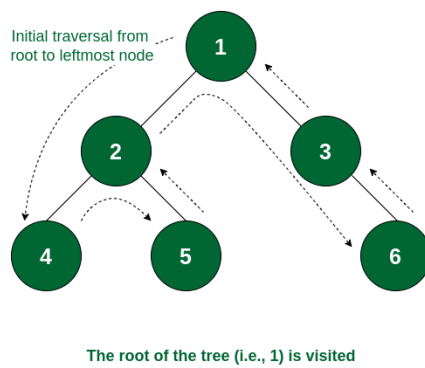

6 has no subtrees. So it is visited

Step 5:

Step 6:

OUTPUT: 4 -> 5 -> 2 -> 6 -> 3 -> 1.

Pre-order Traversal of Binary Tree (Root-Left-Right)

EXAMPLE:

Step 1:

Root of the tree (i.e., 1) is visited

Step 2:

Root of left subtree of 1 (i.e., 2) is visited

Step 3:

Left child of 2 (i.e., 4) is visited

Step 4:

Right child of 2 (i.e., 5) is visited

Step 5:

Root of right subtree of 1 (i.e., 3) is visited

Step 6:

3 has no left subtree. So right subtree is visited

OUTPUT: 1 -> 2 -> 4 -> 5 -> 3 -> 6.

```

OUTPUT:

GRAPH

🚦 **Graph Data Structure** is a non-linear data structure consisting of vertices and edges. It is useful in fields such as social network analysis, recommendation systems, and computer networks. In the field of sports data science, graph data structure can be used to analyze and understand the dynamics of team performance and player interactions on the field.

COMPONENTS OF GRAPH

Vertices: Vertices are the fundamental units of the graph. Sometimes, vertices are also known as vertex or nodes. Every node/vertex can be labeled or unlabelled.

Edges: Edges are drawn or used to connect two nodes of the graph. It can be ordered pair of nodes in a directed graph. Edges can connect any two nodes in any possible way. There are no rules. Sometimes, edges are also known as arcs. Every edge can be labelled/unlabelled.

REPRESENTATION OF GRAPHS

Here are the two most common ways to represent a graph :

1. Adjacency Matrix
2. Adjacency List

1. Adjacency Matrix: An adjacency matrix is a way of representing a graph as a matrix of boolean (0's and 1's).

- If there is an edge from vertex i to j , mark $\text{adjMat}[i][j]$ as 1.
- If there is no edge from vertex i to j , mark $\text{adjMat}[i][j]$ as 0.

2. Adjacency List: An array of Lists is used to store edges between two vertices. The size of array is equal to the number of vertices (i.e, n). Each index in this array represents a specific vertex in the graph. The entry at the

index i of the array contains a linked list containing the vertices that are adjacent to vertex i .

- `adjList[0]` will have all the nodes which are connected (neighbour) to vertex 0.
- `adjList[1]` will have all the nodes which are connected (neighbour) to vertex 1 and so on.

TYPES OF GRAPHS

1. Null Graph: A graph is known as a null graph if there are no edges in the graph.

Null Graph

2. Trivial Graph: Graph having only a single vertex, it is also the smallest graph possible.

Trivial Graph

3. Undirected Graph: A graph in which edges do not have any direction. That is the nodes are unordered pairs in the definition of every edge.

Undirected Graph

4. Directed Graph: A graph in which edge has direction. That is the nodes are ordered pairs in the definition of every edge.

Directed Graph

ADJACENCY LIST

CODE:

```
def print_adj_list(graph):
    print("Adjacency List")
    for node, neighbours in enumerate(graph):
        print(f"{node}: {' '.join(map(str, neighbours))}")

def print_adj_matrix(matrix):
    print("Adjacency Matrix:")
    for row in matrix:
        print(" ".join(map(str, row)))

adj_list = [
    [1, 2], # neighbours of node 0
```

```

    [2],    # neighbours of node 1
    [0, 3], # neighbours of node 2
    [3]     # neighbours of node 3
]
edges = [
    (0, 1),
    (0, 2),
    (1, 2),
    (2, 0),
    (2, 3),
    (3, 3)
]
num_nodes = len(adj_list)
adj_matrix = [[0] * num_nodes for _ in range(num_nodes)]
for src, dest in edges:
    adj_matrix[src][dest] = 1
print_adj_list(adj_list)
print_adj_matrix(adj_matrix)

```

OUTPUT:

```

1 #Adjacency list in Graph
2 def print_adj_list(graph):

```

LEETCODE

1. There are n kids with candies. You are given an integer array `candies`, where each `candies[i]` represents the number of candies the i th kid has, and an integer `extraCandies`, denoting the number of extra candies that you have. Return a boolean array `result` of length n , where `result[i]` is `true` if, after giving the i th kid all the `extraCandies`, they will have the greatest number of candies among all the kids, or `false` otherwise.

Note that multiple kids can have the greatest number of candies.

CODE:

class Solution:

```

def kidsWithCandies(self, candies: List[int], extraCandies: int) -> List[bool]:
    max_candies = max(candies) # Find the maximum candies any kid has
    result = [] # Initialize the result list
    for candy in candies:
        # Check if giving the current kid all the extra candies makes them have
        the most candies
        if candy + extraCandies >= max_candies:
            result.append(True) # If true, append True to result
        else:
            result.append(False) # Otherwise, append False to result
    return result # Return the result list

```

OR

class Solution:

```

def kidsWithCandies(self, candies: List[int], extraCandies: int) -> List[bool]:
    result_lst=[]
    max_num=max(candies)

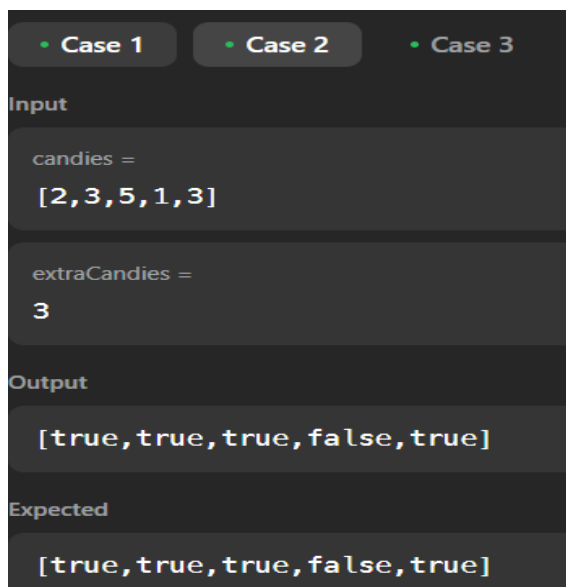

```

```

for num in candies:
    result_lst.append(num+extraCandies>=max_num)
return result_lst

```

OUTPUT:

BREADTH-FIRST SEARCH

CODE:

#Breadth-first search

```
def bfs(graph, start_node):
```

```
    visited = set()    # To keep track of visited nodes
```

```
    queue = [start_node] # Initialize the queue with the start node
```

```
    result = []        # To store the BFS traversal order
```

```
    while queue:
```

```
        node = queue.pop(0) # Dequeue a node from the front of the queue
```

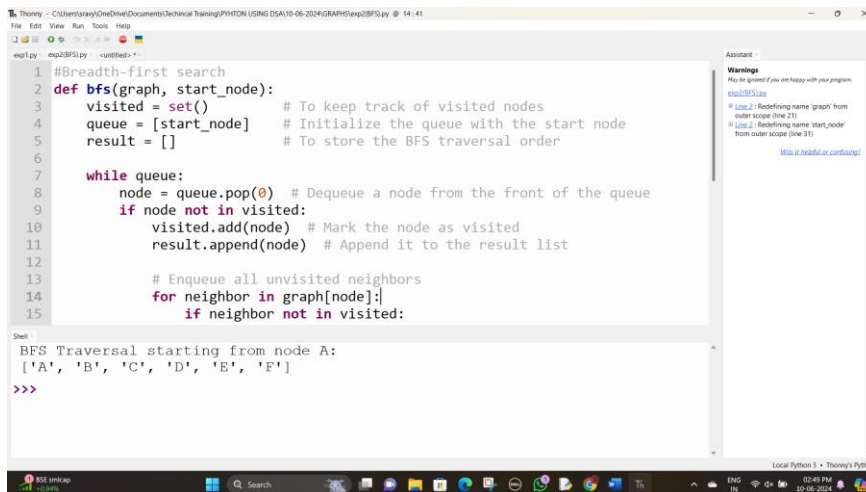

```
    if node not in visited:
        visited.add(node) # Mark the node as visited
        result.append(node) # Append it to the result list
        # Enqueue all unvisited neighbors
        for neighbor in graph[node]:
            if neighbor not in visited:
                queue.append(neighbor)
    return result

# Define the graph using an adjacency list representation
graph = {
    'A': ['B', 'C'],
    'B': ['A', 'D', 'E'],
    'C': ['A', 'F'],
    'D': ['B'],
    'E': ['B', 'F'],
    'F': ['C', 'E']
}

# Define the start node for BFS traversal
start_node = 'A'

# Print the result of BFS traversal
print("BFS Traversal starting from node A:")
print(bfs(graph, start_node))
```

OUTPUT:

A screenshot of a Python IDE window titled 'Thonny'. The main editor shows a Python script for Breadth-First Search (BFS). The code defines a function 'bfs' that takes a graph and a start node. It initializes a 'visited' set, a 'queue' with the start node, and an empty 'result' list. A while loop processes the queue: it dequeues a node, checks if it's visited, adds it to the result, and enqueues its unvisited neighbors. The output window shows the result of a BFS traversal starting from node 'A' on a graph with nodes 'A', 'B', 'C', 'D', 'E', and 'F'. The output is the list ['A', 'B', 'C', 'D', 'E', 'F'].

```
1 #Breadth-first search
2 def bfs(graph, start_node):
3     visited = set() # To keep track of visited nodes

6
7     while queue:
8         node = queue.pop(0) # Dequeue a node from the front of the queue
9         if node not in visited:
10             visited.add(node) # Mark the node as visited
11             result.append(node) # Append it to the result list
12
13             # Enqueue all unvisited neighbors
14             for neighbor in graph[node]:
15                 if neighbor not in visited:
```

Shell:

```
BFS Traversal starting from node A:
['A', 'B', 'C', 'D', 'E', 'F']
>>>
```

DEPTH-FIRST SEARCH

CODE:

#Depth-first search

```
def dfs(graph, start_node):
```

```
    visited = set() # To keep track of visited nodes
```

```
    stack = [start_node] # Initialize the stack with the start node
```

```
    result = [] # To store the BFS traversal order
```

```
    while stack:
```

```
        node = stack.pop() # Destack a node from the front of the stack
```

```
        if node not in visited:
```

```
            visited.add(node) # Mark the node as visited
```

```
            result.append(node) # Append it to the result list
```

```
            # Enstack all unvisited neighbors
```

```
            for neighbor in graph[node]:
```

```
                if neighbor not in visited:
```

```
                    stack.append(neighbor)
```

```
    return result
```

Define the graph using an adjacency list representation

```
graph = {  
    'A': ['B', 'C'],  
    'B': ['A', 'D', 'E'],  
    'C': ['A', 'F'],  
    'D': ['B'],  
    'E': ['B', 'F'],  
    'F': ['C', 'E']  
}
```

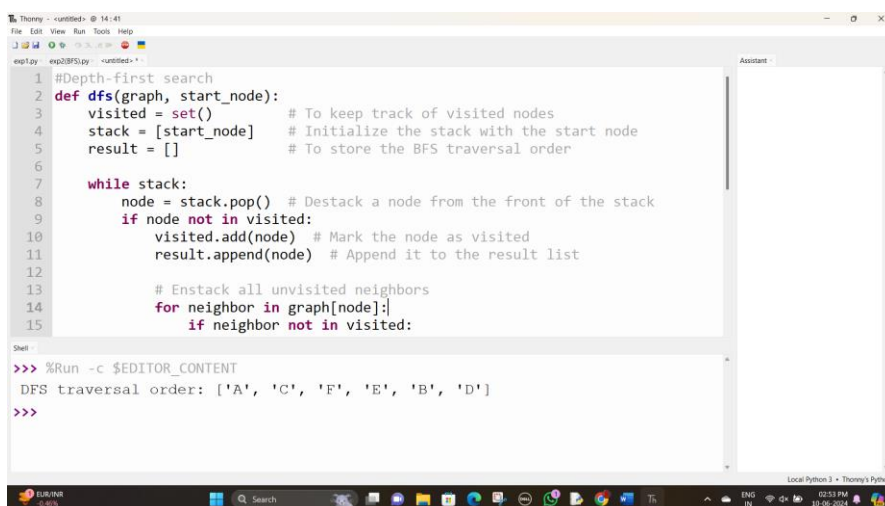

Define the start node for BFS traversal

```
start_node = 'A'
```

Print the result of BFS traversal

```
print("DFS traversal order:", dfs(graph, start_node))
```

OUTPUT:

A screenshot of a Python IDE window titled 'Thonny - untitled-1 @ 14:41'. The editor shows a Depth-First Search (DFS) implementation. The code defines a function 'dfs' that takes a graph and a start node. It uses a stack to traverse the graph, marking visited nodes and appending them to a result list. The graph is defined as an adjacency list with nodes A through F. The start node is 'A'. The output of the program is printed in the shell: 'DFS traversal order: ['A', 'C', 'F', 'E', 'B', 'D']'. The IDE interface includes a menu bar, a toolbar, and a taskbar at the bottom showing the Windows taskbar with various application icons and the system clock at 02:33 PM on 19-06-2024.

```
1 #Depth-first search  
2 def dfs(graph, start_node):  
3     visited = set() # To keep track of visited nodes  
4     stack = [start_node] # Initialize the stack with the start node  
5     result = [] # To store the BFS traversal order  
6  
7     while stack:  
8         node = stack.pop() # Destack a node from the front of the stack  
9         if node not in visited:  
10             visited.add(node) # Mark the node as visited  
11             result.append(node) # Append it to the result list  
12  
13             # Enstack all unvisited neighbors  
14             for neighbor in graph[node]:  
15                 if neighbor not in visited:
```

```
